A simplified structure of the *npn* transistor.
A simplified structure of the $pnp$ transistor.
Current flow in an *npn* transistor biased to operate in the active mode, (Reverse current components due to drift of thermally generated minority carriers are not shown.)
Current flow in an pnp transistor biased to operate in the active mode.
The $i_C-v_{CB}$ characteristics for an npn transistor in the active mode.
(a) Conceptual circuit for measuring the $i_C-v_{CE}$ characteristics of the BJT.

(b) The $i_C-v_{CE}$ characteristics of a practical BJT.
(a) Conceptual circuit to illustrate the operation of the transistor of an amplifier.
(b) The circuit of (a) with the signal source $v_{be}$ eliminated for dc (bias) analysis.
Linear operation of the transistor under the small-signal condition: A small signal $v_{be}$ with a triangular waveform is superimposed on the dc voltage $V_{BE}$. It gives rise to a collector signal current $i_c$, also of triangular waveform, superimposed on the dc current $I_C$. $I_c = g_m v_{be}$, where $g_m$ is the slope of the $i_c - v_{BE}$ curve at the bias point $Q$.

Two slightly different versions of the simplified hybrid-Π model for the small-signal operation of the BJT. The equivalent circuit in (a) represents the BJT as a voltage-controlled current source (a transconductance amplifier) and that in (b) represents the BJT as a current-controlled current source (a current amplifier).
Two slightly different versions of what is known as the *T model* of the BJT. The circuit in (a) is a voltage-controlled current source representation and that in (b) is a current-controlled current source representation. These models explicitly show the emitter resistance $r_e$ rather than the base resistance $r_{\Pi}$ featured in the hybrid-$\pi$ model.

\[ g_m = I_C / V_T \]
\[ r_e = \frac{V_T}{I_E} = \frac{\alpha}{g_m} \]
Junction Field-Effect Transistors

\[ i_D \quad v_{DS} \]

\[ I_{DSS} \quad v_{GS}=0 \]

\[ v_{GS}=-1 \quad v_{DG} > -V_p \quad \text{Pinch-off} \]

\[ v_{GS}=V_p \]

\[ v_{DG} > V_p \]

\[ v_{SG}=-V_p \]

\[ v_{SG}=0 \]

\[ v_{SG}=-1 \quad v_{GD} > V_p \quad \text{Pinch-off} \]
Junction Field-Effect Transistors

Triod (VCR) Region

\[ i_D = I_{DSS} \left[ 2 \left( 1 - \frac{v_{GS}}{V_p} \right) \left( \frac{v_{DS}}{V_p} \right) - \left( \frac{v_{DS}}{V_p} \right)^2 \right] \]

\[ r_{DS} = \frac{v_{DS}}{i_D} \bigg|_{v_{DS} = small} = \left[ \frac{2I_{DSS}}{-V_p} \left( 1 - \frac{v_{GS}}{V_p} \right) \right]^{-1} \]

Boundary

\[ v_{DG} = -V_p \]

\[ i_D = I_{DSS} \left( \frac{v_{DS}}{V_p} \right)^2 \]

Pinch-Off Region

\[ i_D = I_{DSS} \left( 1 - \frac{v_{GS}}{V_p} \right)^2 \]
MOSFETs
Physical structure of the enhancement-type NMOS transistor: (a) perspective view; (b) cross section. Typically $L = 1$ to 10 μm, $W = 2$ to 500 μm, and the thickness of the oxide layer is in the range of 0.02 to 0.1 μm.
The enhancement-type NMOS transistor with a positive voltage applied to the gate. An n channel is induced at the top of the substrate beneath the gate.
The drain current $i_D$ versus the drain-to-source voltage $v_{DS}$ for an enhancement-type NMOS transistor operated with $v_{GS} > V_t$. 
Cross section of a CMOS integrated circuit. Note that the PMOS transistor is formed in a separate $n$-type region, known as an $n$ well. Another arrangement is also possible in which an $n$-type body is used and the $n$ device is formed in a $p$ well.
(a) An n-channel enhancement-type MOSFET with $v_{GS}$ and $v_{DS}$ applied and with the normal directions of current flow indicated.  

(b) The $i_D - v_{DS}$ characteristics for a device with $V_t = 1$ V and $k'_n(W/L) = 0.5$ mA/V$^2$. 
The $i_D - v_{GS}$ characteristic for an enhancement-type NMOS transistor in saturation ($V_t = 1$ V and $k'_n(W/L) = 0.5$ mA/V$^2$).
Large-signal equivalent circuit model of the $n$-channel MOSFET in saturation, incorporating the output resistance $r_o$. The output resistance models the linear dependence of $i_D$ on $v_{DS}$ and is given by $r_o \approx V_A/I_D$. 
Conceptual circuit utilized to study the operation of the MOSFET as an amplifier.
Small-signal operation of the enhancement MOSFET amplifier.
Small-signal models for the MOSFET: (a) neglecting the dependence of $i_D$ on $v_{DS}$ in saturation (channel-length modulation effect); and (b) including the effect of channel-length modulation modeled by output resistance $r_o = |V_A|/I_D$.
